

## Atomic Structure, Periodic Table, & Lewis Structures

The image shows a standard periodic table of elements. It is organized into seven rows and several columns. Each element is represented by a small box containing its chemical symbol, atomic number, and name. The table is color-coded by groups: alkali metals (purple), alkaline earth metals (orange), transition metals (green), metalloids (yellow), nonmetals (red), and noble gases (blue). The title "Periodic Table of the Elements" is centered at the top of the table.

## Dalton's Atomic Theory

1. All matter is composed of extremely small particles called \_\_\_\_\_
2. All atoms of a given element are \_\_\_\_\_, having the same size, mass, and chemical properties. Atoms of a specific element are \_\_\_\_\_ from other elements
3. Atoms cannot be \_\_\_\_\_, \_\_\_\_\_, or \_\_\_\_\_
4. Different atoms combine in simple whole number \_\_\_\_\_ to form compounds
5. In a \_\_\_\_\_, atoms are separated, combined, or rearranged

## JJ Thomson

- JJ used the \_\_\_\_\_ experiment to determine the \_\_\_\_\_ to \_\_\_\_\_ ratio of an electron.
- He identified the first subatomic particle, the \_\_\_\_\_
- He proposed the \_\_\_\_\_ model of the atom
- Credited Thomson for discovering the \_\_\_\_\_

## Robert Millikan

- Millikan is noted for his famous Millikan's \_\_\_\_\_
- This experiment determined the \_\_\_\_\_ and the \_\_\_\_\_ of an electron

## Earnest Rutherford

- Rutherford's \_\_\_\_\_ Experiment helped to determine the existence of the \_\_\_\_\_
- Rutherford proposed that the nucleus was \_\_\_\_\_ and \_\_\_\_\_ charged
- Proposed the \_\_\_\_\_ model which stated that there was a nucleus with a positive charge and electrons around the outside

## James Chadwick

- Chadwick showed that the nucleus also contained \_\_\_\_\_
- He is credited for the discovery of the \_\_\_\_\_

## Basic Definitions

- \_\_\_\_\_ – smallest unit of an element that retains the properties of that element

## Protons, Neutrons, & Electrons

- **Protons**
  - \_\_\_\_\_ charge
  - found in the \_\_\_\_\_
- **Neutrons**
  - \_\_\_\_\_ charge
  - found in the \_\_\_\_\_
- **Electrons**
  - \_\_\_\_\_ charge
  - found on the \_\_\_\_\_ of the nucleus
- **Nucleus**
  - made up of \_\_\_\_\_ and \_\_\_\_\_
  - overall \_\_\_\_\_ charge

## Atomic Structure

TABLE 2.1. Comparison of the Proton, Neutron, and Electron.

Particle	Charge	Mass (amu)
Proton	Positive (1+)	1.0073
Neutron	None (neutral)	1.0087
Electron	Negative (1-)	$5.486 \times 10^{-4}$

## Atomic Numbers

- \_\_\_\_\_ (Z) - number of \_\_\_\_\_ in the nucleus of an atom of that element.
- The number of protons determines the \_\_\_\_\_ of an element
- The number of protons for an element \_\_\_\_\_ be changed.

## Atomic Numbers

- Atoms have no overall electrical charge so the number of \_\_\_\_\_ must equal the number of \_\_\_\_\_ .
- The number of electrons can be changed when determining the charge of an \_\_\_\_\_ .

## Masses

- The sum of the protons and neutrons in the nucleus is the \_\_\_\_\_ (A) of that particular atom.
- Isotopes of an element have different mass numbers because they have different numbers of \_\_\_\_\_

## Isotopes

- When writing isotopes, the atomic number (or number of protons) will appear at the \_\_\_\_\_
- The mass number (number of protons plus neutrons) will appear at the \_\_\_\_\_
- The element symbol will appear to the \_\_\_\_\_
- The different number of neutrons has NO bearing on chemical reactivity

$$\begin{array}{c} \text{mass number} \\ \text{atomic number} \end{array} \text{X}$$

## Writing the Names of Isotopes

- Write the name of the element – the mass number
- For example  $^{12}_6\text{C}$  would be named:

## Try the following

Name	Symbol	# Protons	# Neutrons	# Electrons	Mass #
Carbon - 11					
	$^{197}_{79}\text{Au}$				
		1	2		
				25	55
Oxygen - 15					

## Try this one

Name	Symbol	# Protons	# Neutrons	# Electrons	Mass #
Iodine - 130					

## Atomic Mass

- \_\_\_\_\_-weighted average mass of all the naturally occurring isotopes of that element.

## Calculating Atomic Mass

- Copper exists as a mixture of two isotopes. The lighter isotope (Cu-63), with 29 protons and 34 neutrons, makes up 69.17% of copper atoms. The heavier isotope (Cu-65), with 29 protons and 36 neutrons, constitutes the remaining 30.83% of copper atoms. Calculate the atomic mass of Copper.

## Calculating Atomic Mass

## Try this one...

Calculate the atomic mass of germanium.

Isotope	Abundance (%)	Atomic Mass (amu)
Germanium-70	21.23	69.924
Germanium-72	27.66	71.922
Germanium-73	7.73	72.923
Germanium-74	35.94	73.921
Germanium-76	7.44	75.921

### You can tell many things from an isotope formula

- Hydrogen has three naturally occurring isotopes in nature: Hydrogen – 1, Hydrogen – 2, and Hydrogen – 3.
  - Which is the most abundant in nature?
  - Which is the heaviest?

### Periodic Table

- \_\_\_\_\_ – arrangement of elements in order of increasing atomic number with elements having similar properties in vertical columns
  - \_\_\_\_\_ – vertical columns
  - \_\_\_\_\_ – horizontal rows

### Group Names

Group	Name
1A	
2A	
3A	
4A	
5A	
6A	
7A	
8A	

### Groups

- The group tells you the number of \_\_\_\_\_
- Valence electrons - electrons in the \_\_\_\_\_ shell of the atom

## Characteristics

- Elements in the same group exhibit similar chemical characteristics due to the fact that they all have the same number of \_\_\_\_\_.
- The most stable number of valence electrons is \_\_\_\_\_.
- This is called an \_\_\_\_\_.

## Physical States and Classes of the Elements

- The majority of the elements are \_\_\_\_\_. They occupy the entire left side and center of the periodic table.
- \_\_\_\_\_ occupy the upper-right-hand corner.
- \_\_\_\_\_ are located along the boundary between metals and nonmetals.

## Metals

- \_\_\_\_\_ are elements that have luster, conduct heat and electricity, and usually bend without breaking.
- All metals except \_\_\_\_\_ are solids at room temperature.

## Transition Metals

- The elements in Groups B of the periodic table are called the \_\_\_\_\_.
- All transition elements are \_\_\_\_\_.
- Many transition metals can have more than one charge.

## Non Metals

- Most \_\_\_\_\_ don't conduct electricity, are much poorer conductors of heat than metals, and are brittle when solid.
- Many are gases at room temperature; those that are solids lack the luster of metals.

## Metalloids

- \_\_\_\_\_ have some chemical and physical properties of metals and other properties of nonmetals.

## Nuclear vs. Chemical

- |  |   |
|--|---|
| <ul style="list-style-type: none"><li>• Occurs when bonds are broken and formed</li><li>• Atoms remain unchanged, but they may be rearranged</li><li>• Involve only valence electrons</li><li>• Have small energy changes</li><li>• Reaction rates are influenced by temperature, pressure, concentration, and catalysts</li></ul> | <ul style="list-style-type: none"><li>• Occurs when nuclei emit particles and/or rays</li><li>• Atoms of one element are converted into another element</li><li>• May involve protons, neutrons, or electrons</li><li>• Have large energy changes</li><li>• Reaction rates are not affected</li></ul> |
|--|---|

## Types of Radiation

- The three most common types of radiation are alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ).

## Deflection

- The effect of an electric field on three types of radiation is shown.

## Nuclear Reactions

- Write the reaction for radium - 226 converting into radon-222
- Write the reaction of carbon-14 decaying into nitrogen - 14
- Write the reaction of uranium-238 undergoing alpha and gamma decay

## Fission and Fusion

- \_\_\_\_\_ – splitting the nucleus into fragments
  - Releases large amounts of energy
  - Nuclear power plants use fission to generate power
- \_\_\_\_\_ – combining of atomic nuclei
  - Release large amounts of energy
  - Require extremely high temperatures
  - The lowest temperature possible is 40,000,000 K
  - Known to occur on the sun
